

HTTP Headers and JSON

Backend development study note for document retrieval and grounded question-answering practice.

Headers

HTTP headers carry metadata about a request or response. Content-Type identifies the media type of the message body, such as application/json. Accept indicates which response media types the client can handle. Authorization commonly carries credentials or a bearer token.

JSON

JSON (JavaScript Object Notation) is a text format for exchanging structured data. JSON objects contain key-value pairs. Servers should validate incoming data rather than assuming that syntactically valid JSON is semantically correct.

Example

A request may include Content-Type: application/json and a body such as {"name":"Ada","active":true}. The server should validate required fields and types.
