

HTTPS and TLS

Backend development study note for document retrieval and grounded question-answering practice.

HTTPS

HTTPS is HTTP carried over Transport Layer Security (TLS). TLS helps protect data in transit by providing encryption, server authentication, and integrity protection.

What HTTPS does not guarantee

HTTPS does not by itself guarantee that an application is secure. Applications still need authorization checks, input validation, safe secret handling, and secure application design.

Certificates

In typical HTTPS connections, a server presents a certificate that the client validates according to its trust configuration. Certificate validation helps the client authenticate the server endpoint.
